01 Timeline

02 Frontend

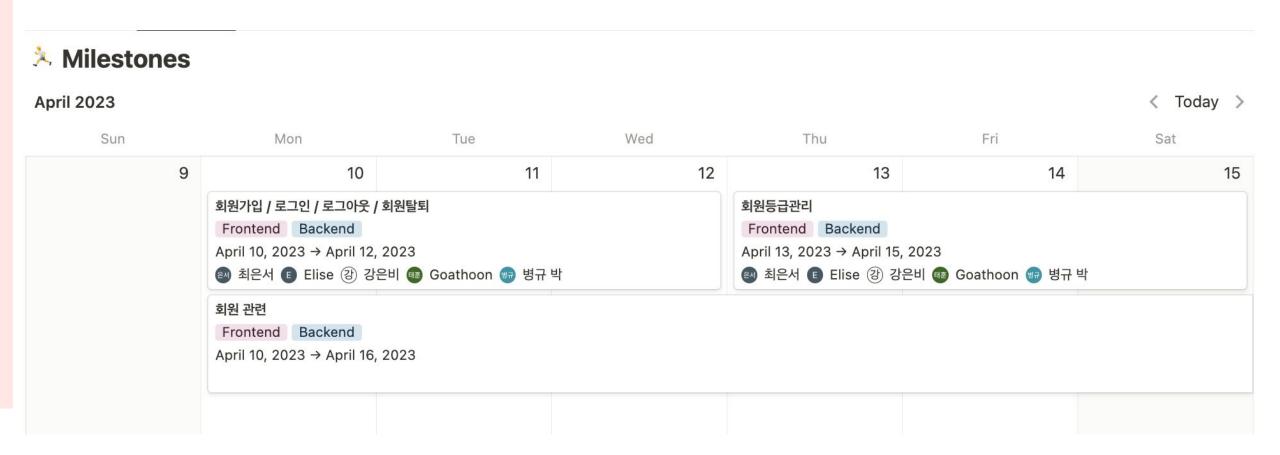

03 Backend / Data

04 Next week

Part 1. Timeline (This Week)

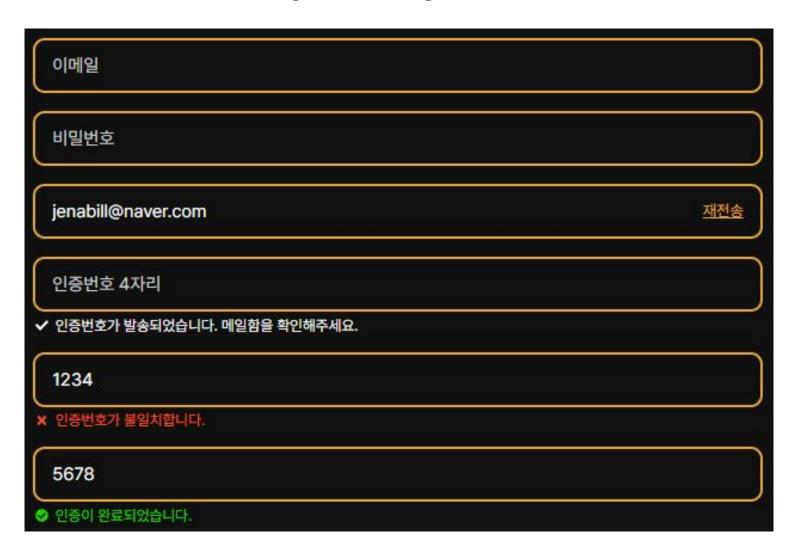

Part 2. Page Routing Setting

Routing Path	Page
	Home page
/login	Login page
/register	Registration page
/recipe	Recipe page
/community	Community page
/cocktailbar	Cocktail Bar Map page
/mypage	My Page

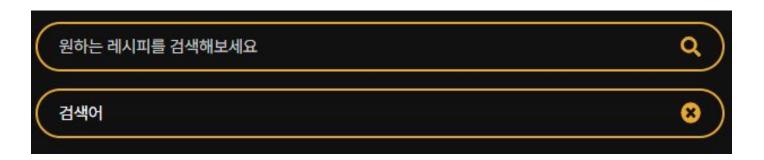

Part 2. Reusable Components (1)

Input Component

Part 2. Reusable Components (2)

Search Bar Component

MemberBadge Component

DropdownMenu Component

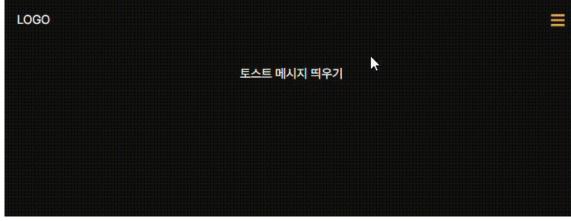

Part 2. Reusable Components (3)

ToastMessage Component

Desktop Version

Mobile Version

Part 2. Login Page

회원가입 LOGO 칵테일 레시피 커뮤니티 칵테일 바 지도 로고 로그인 후 다양한 콘텐츠를 즐겨보세요 이메일 비밀번호 비밀번호를 잊으셨나요? 회원가입

Part 2. Registration Page

LOGO 커뮤니티 칵테일 레시피 칵테일 바 지도 회원가입 회원가입 이메일 인증번호 전송 인증번호 인증하기 비밀번호 ✓ 8자 이상 16자 미만, 영어 및 숫자 각각 1개 이상 포함 비밀번호 확인 닉네임 중복확인

Part 2. Proxy Setting

Frontend (Browser)

http://localhost:3000

Send HTTP Request

Backend (Server)

http://localhost:3030

ERROR

"Cross-Origin Request Blocked: The Same Origin Policy disallows reading the remote resource at \$somesite"

Part 2. Proxy Setting

Frontend (Browser)

http://localhost:3000

Proxy Server

http://localhost:3000

Backend (Server)

http://localhost:3030

Part 2. Token Management

Token	Expire Time	Storage Location
Access token	After 1 Hour	Local Storage
Refresh token	After 14 Days	Cookie

Part 3. Setting - ORM(Objective Relational Mapping

'Sequelize' & 'Sequelize-auto' module

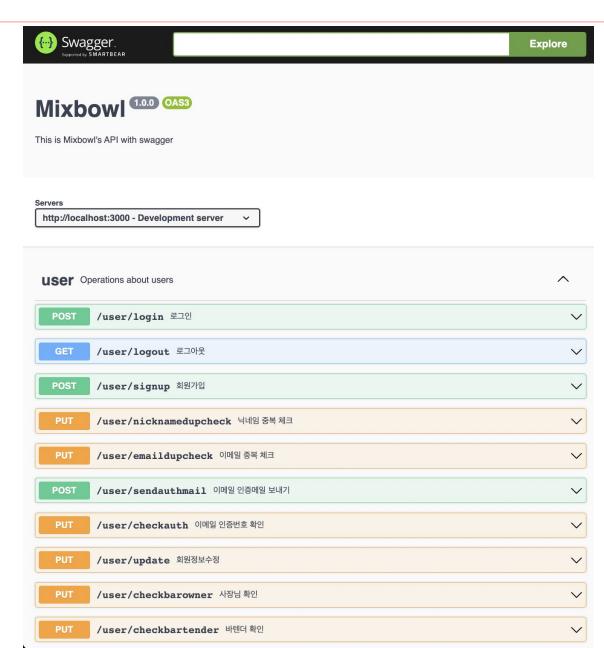

```
s init-models.js > ...
backend > src > models > Js USER.js > 😭 USER > 😭 init
       import sequelize from 'sequelize';
                                                     inction initModels(sequelize) {
       const { Model, Sequelize } = _sequelize;
                                                     'OST.init(sequelize, DataTypes);
                                                     : = _POST_LIKE.init(sequelize, DataTypes);
       export default class USER extends Model {
                                                     . = _POST_REPL.init(sequelize, DataTypes);
         static init(sequelize, DataTypes) {
                                                     RECIPE.init(sequelize, DataTypes);
         return super.init({
                                                     IKE = RECIPE LIKE.init(sequelize, DataTypes);
                                                     JSER.init(sequelize, DataTypes);
             autoIncrement: true,
             type: DataTypes.INTEGER,
                                                     igsTo(POST, { as: "PNO_POST", foreignKey: "PNO"});
             allowNull: false,
                                                     DST_LIKE, { as: "POST_LIKEs", foreignKey: "PNO"});
            primaryKey: true
                                                     igsTo(POST, { as: "PNO_POST", foreignKey: "PNO"});
          NICKNAME: {
                                                     DST_REPL, { as: "POST_REPLs", foreignKey: "PNO"});
                                                     RECIPE, { as: "RNO_RECIPE", foreignKey: "RNO"});

            allowNull: false
                                                     :CIPE_LIKE, { as: "RECIPE_LIKEs", foreignKey: "UNO"});
```

Part 3. API Documentation

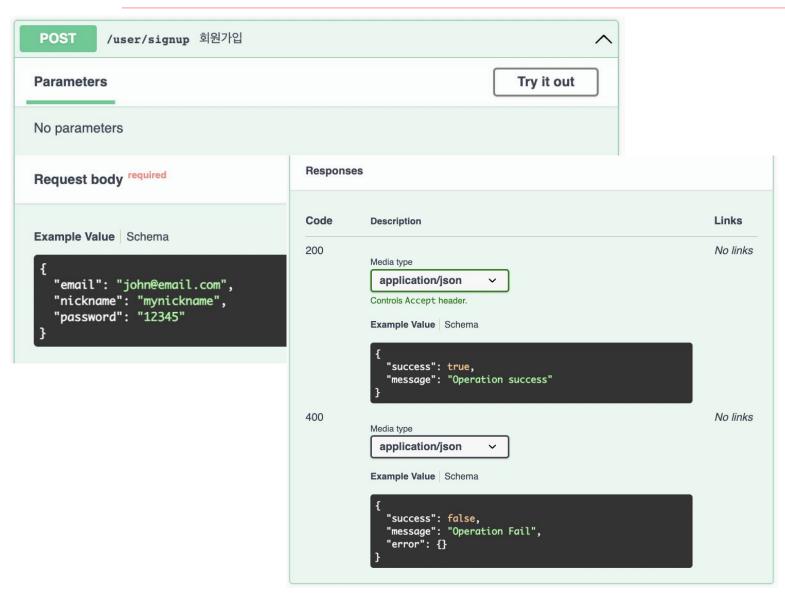

'Swagger' module

http://localhost:3030/api-docs/

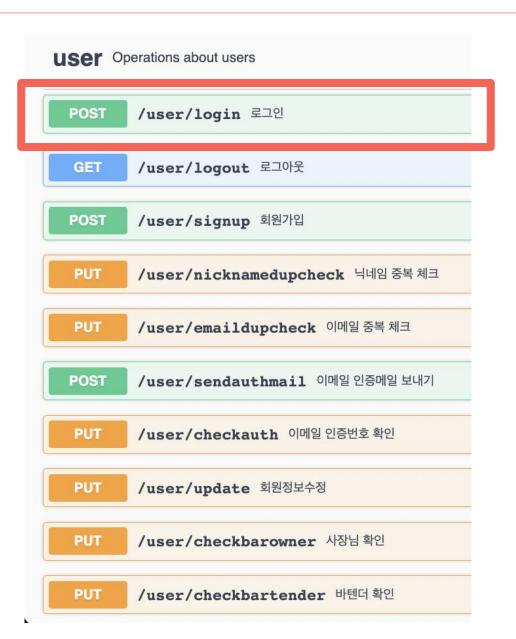

Part 3. API Documentation

'yaml' file

```
backend > src > swagger > 🖹 user.yaml > ...
      paths:
        /user/login:
          post:
              - user
            summary: 로그인
            description: ''
            operationId: loginUser
             requestBody:
              required: true
                application/json:
                   schema:
                     $ref: '#/components/schemas/User'
               '200':
                description: ''
                  application/json:
                     schema:
                       $ref: '#/components/schemas/Success'
               '400':
                description: ''
                  application/json:
                     schema:
                       $ref: '#/components/schemas/Fail'
```

Part 3. Implement

Part 3. Implement - SQL module

export default sql;

- getToken

To get Refresh Token on USER's DB

namedupcheck

To check USER's nickname duplication

- emaildupcheck

To check USER's email duplication

signupUser

To sign up on DB

loginUser

To login by checking USER's table

```
loginUser: async (req) => {
 const { email, password } = req.body;
 try {
   // const [username] = await promisePool.query()
   // SELECT NICKNAME FROM Mixbowl.USER WHERE '${email}' = EMAIL AND '${password}' = PASSWORD;
   const {dataValues} = await USER.findOne({ where: { email : `${email}`,password:`${password}` } });
   const username = dataValues["NICKNAME"];
   if (username.length === 0) {
     console.log("hi");
     throw new Error("Invalid Info User");
   //UNO 도 같이 포함
   const accessToken = await jwt module.sign(username[0]["NICKNAME"]);
   const refreshToken = await jwt module.refresh();
   //refresh token sql 업데이트
   await promisePool.query(
     UPDATE USER SET TOKEN = '${refreshToken}' WHERE NICKNAME = '${username}';
   `);
   return
     code: 200,
     message: "토큰이 발급되었습니다.",
     token: {
       accessToken,
       refreshToken,
   };
   catch (error) {
   console.log(error.message);
   return {
     code: 401,
```

Part 3. Implement - JWT module

```
export function sign(username)
 // Access 토큰 생성 코드
 const payload = {
   type: "JWT",
   nickname: username,
 return jwt.sign(payload, process.env.SECRET KEY, {
   expiresIn: "1h",
   issuer: "MixBowl",
  });
export function accessVerify(token)
 //Access 토큰 확인 코드
 let decoded = null;
 try {
   decoded = jwt.verify(token, process.env.SECRET KEY);
   return {
     ok: true,
     nickname: decoded.nickname[0]["NICKNAME"],
  catch (error) {
   return {
     ok: false,
     message: error.message,
    };
```

```
export function refresh() {
 // Refresh 토큰 생성 코드
 return jwt.sign({}), process.env.SECRET KEY, {
    expiresIn: "14d",
   issuer: "MixBowl",
  });
//토큰 header에 주고, db 내 refresh 토큰으로 확인
export async function refreshVerify(token, username)
  //Refresh 토큰 확인 코프
 //redis 도입하면 좋을듯
 try {
    const refToken = await sql.getToken(username);
    if (token === refToken) {
     try {
       jwt.verify(token, process.env.SECRET KEY);
       return true;
      } catch (error) {
       return false;
     else {
     return false;
   catch (error) {
   return false;
```

Part 3. Implement - JWT module

```
export const refresh_new = async (req, res) => {
  if (req.headers.authorization && req.headers.refresh) {
   const access = req.headers.authorization;
   const refresh = req.headers.refresh;
   const accessResult = accessVerify(access);
   const decodeAccess = jwt.decode(access);
   if (decodeAccess === null) {
     res.status(401).send({
       ok: false,
       message: "No Authorization for Access Token",
      });
   const refreshResult = refreshVerify(refresh, decodeAccess.nickname);
   if (accessResult.ok === false && accessResult.message === "jwt expired") {
     if (refreshResult.ok === false) {
       res.status(401).send({
         ok: false,
         message: "No Authorization, MAKE A NEW LOGIN",
       });
       else {
       //refresh token이 유효하므로, 새로운 access token 발급
       const newAccessToken = sign(req.body.nickname);
       res.stauts(200).send({
          ok: true.
         nickname: req.body.nickname,
        });
```

Part 3. Implement - Login

```
const {dataValues} = await USER.findOne({ where: { email : `${email}`,password:`${password}` }
const username = dataValues|"NICKNAME"|;
if (username.length === 0) {
 cor sole.log("hi");
                                                                       router.post("/login", async (req, res) => {
 throw new Error("Invalid Info User");
                                                                          const tokens = await sql.loginUser(req, res);
//LING 도 가이 포하
                                                                          IT (LOKENS.COUE :== ZUU) {
                                                                            throw new Error();
const accessToken = await jwt_module.sign(username[0]["NICKNAME"]);
const refreshToken = await jwt module.refresh();
                                                                          const { email } = req.body;
                                                                          //이메일 유효성 검사 함수 정의 필요
                                                                          if (email.length === 0) {
                                                                            throw new Error();
                                               return Token
                                                                          return res.status(200).send({
                                                                            success: true,
                                                                            // nickname: nickname[0]["NICKNAME"],
                                                                            tokens,
                                                                          });
                                                                         } catch (error) {
CHECK USER'S INFORMATION
                                                                          return res.send({ success: false });
                                                                       });
```

Part 4. Timeline (Next Week)
